

Energy demand model for CREEM

Wojciech Adaszynski

The problem

Finding good model for predicting energy consumption of building in the system.

Goals

- A method to calculate energy forecast.
- Efficient algorithm for retrieving and processing data from database.
- Increase in accuracy of our predictions.

Current method

$$\delta = 17.25\%$$

Current method

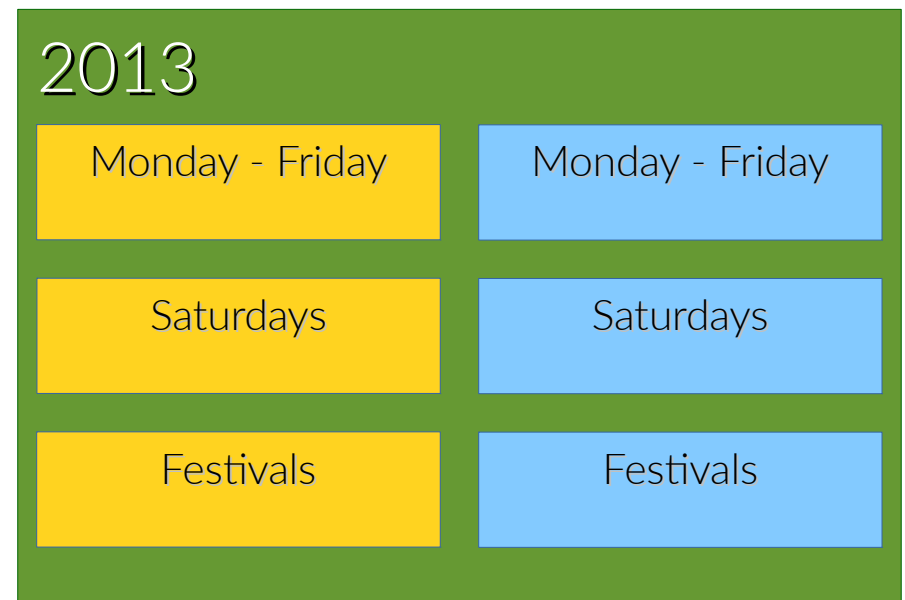

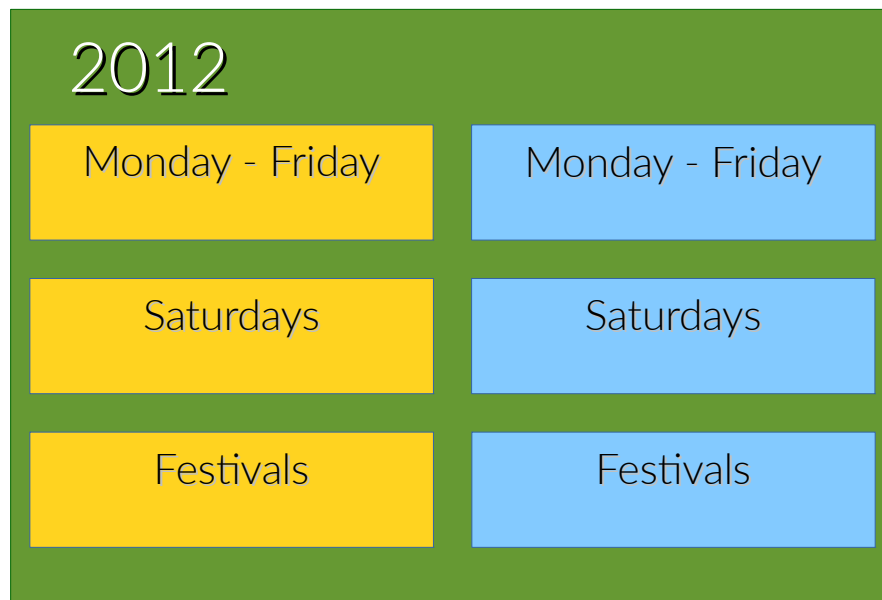

$$\delta = 38\%$$

Key idea

- 1) Find relevant patterns in the consumption
- 2) Cluster data to smaller chunks
- 3) Apply two-variable regression

Key idea

How to divide our measurements?

Key idea

Finding correlation.

$$X = \{x : x = |Internal - temperature|\}$$

$$Y = \{y : y = consumption - Profile\}$$

Key idea

How to improve our model?

- 1) Set division based on HDD/CDD
- 2) Checking variables correlation
- 3) Baseload?

Key idea

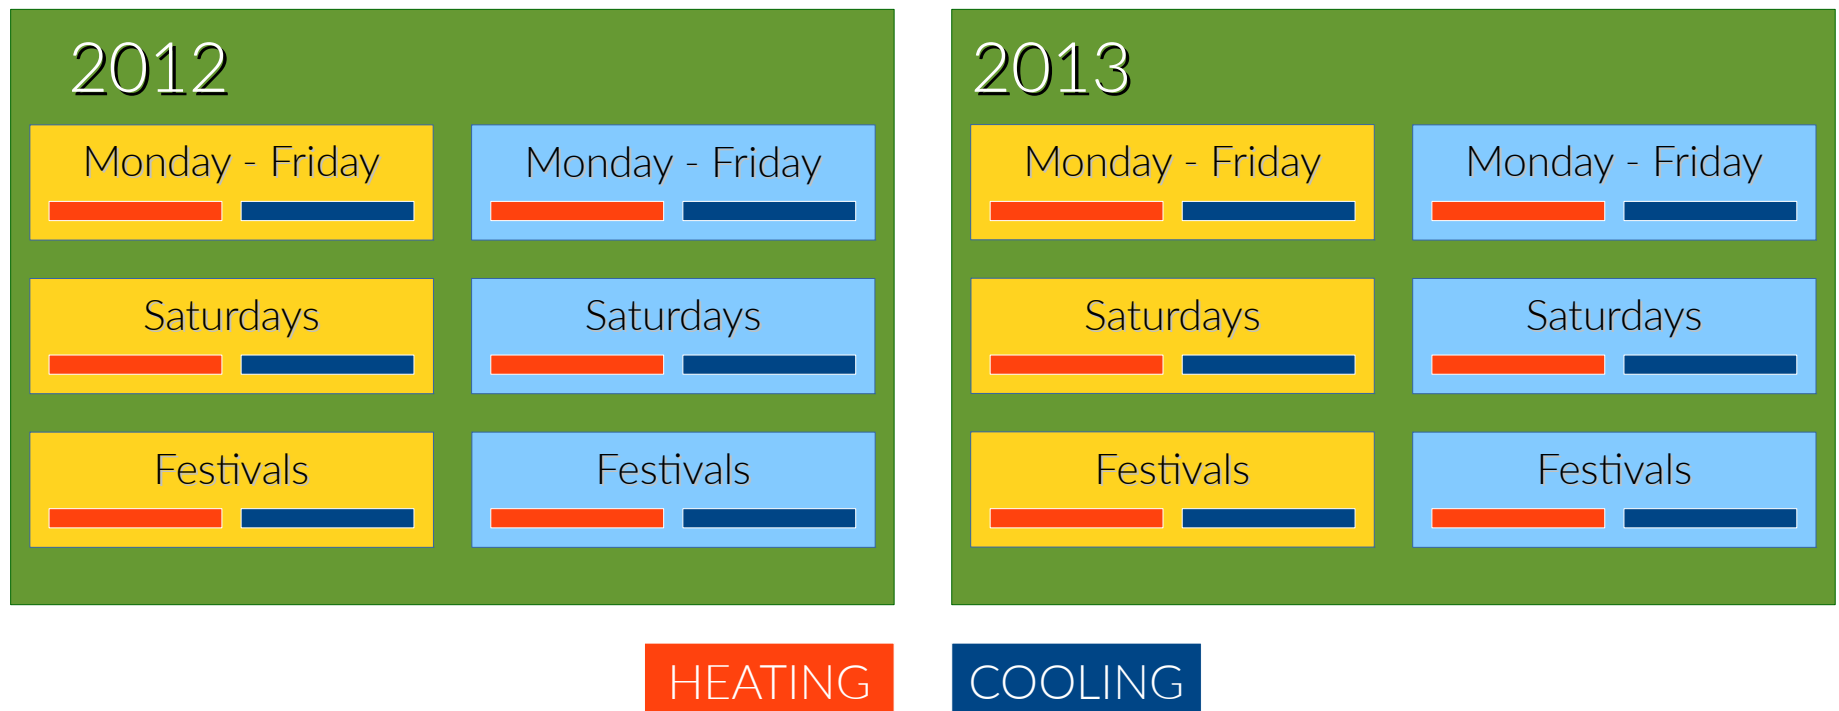

Checking variables correlation

Pearson correlation coefficient throughout the day

Key idea

Set division based on HDD/CDD

Final results

Before: $\delta = 23.3\%$

After: $\delta = 20.2\%$

Future improvements

- 1) Different correlation type (Fouriers 1st polymonial?)
- 2) Subtracting baseload from consumption
- 3) Decision analysis / removing outliers

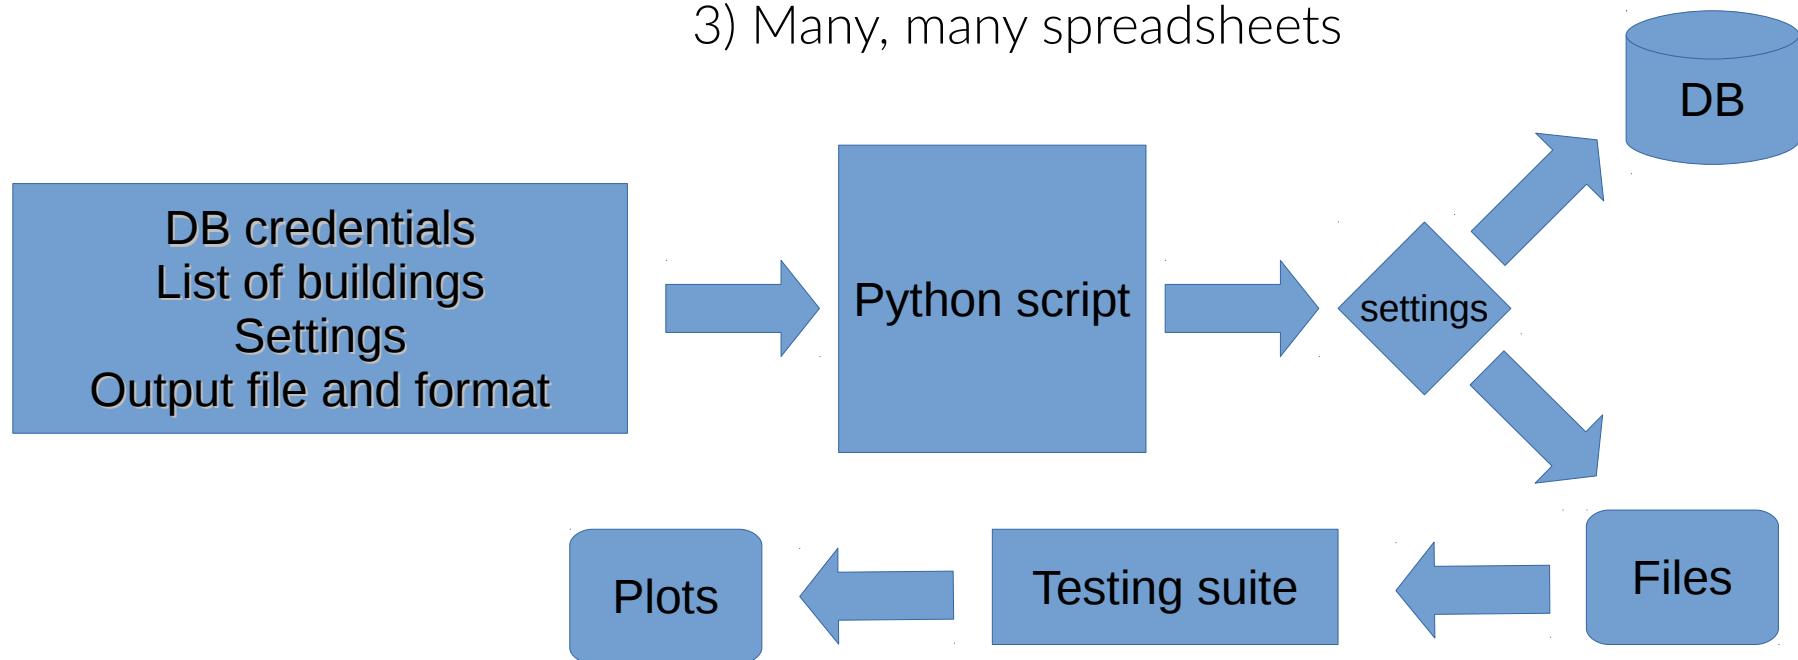

Implementation

1) Python Script for retrieving and calculating data

- mysql connector
- numpy library
- Matplotlib charts

2) Testing suit for results comparison

3) Many, many spreadsheets
